Practice with Fixed and Random Effects of Time in Modeling Within-Person Change

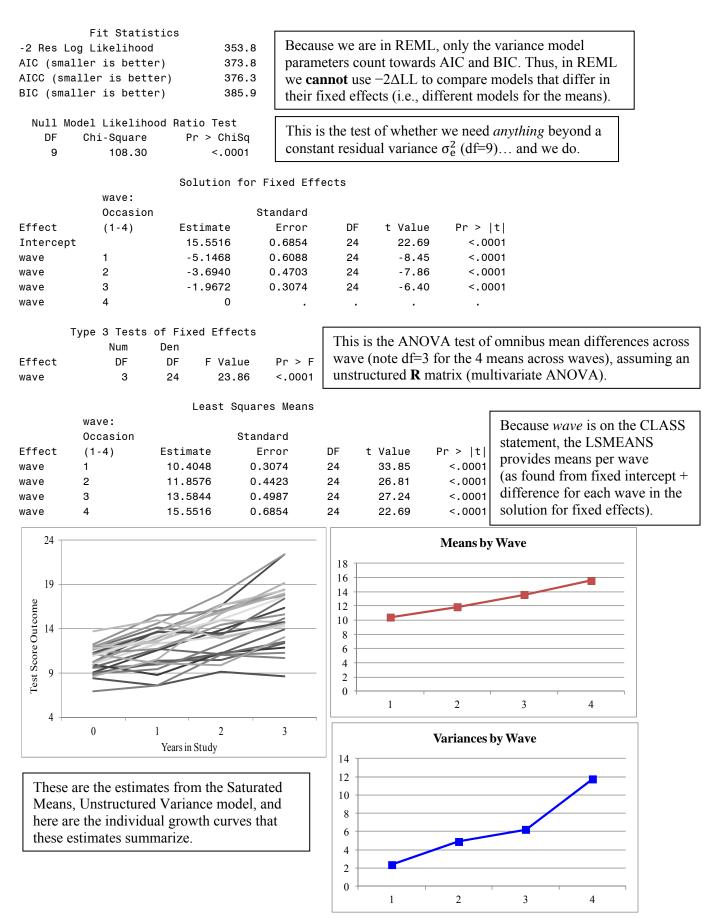

The models for this example come from Hoffman (in preparation) chapter 5. We will be examining the extent to which change in a test score outcome across four annual occasions can be described with fixed and random linear effects of time (indexed by years in study, in which 0 is baseline) in a sample of 25 persons.

SAS Syntax and Output for Data Manipulation:

```
* Location for files to be saved - CHANGE THIS TO YOUR DIRECTORY;
%LET filesave=F:\Example Data\Chapter 5 Data;
LIBNAME filesave "&example.";
* Import data into work library, center time;
DATA example5; SET filesave.example5;
        time = wave - 1; LABEL time= "time: Time in Study (0=1)";
RUN;
```

The **ANSWER KEY** for both the model for the means (via saturated means) and the model for the variances (via unstructured **R** matrix of all possible variances and covariances) is possible to estimate in balanced data:

```
TITLE1 "Saturated Means, Unstructured Variance Model -- the ANSWER KEY";
PROC MIXED DATA=example5 COVTEST NOITPRINT NOCLPRINT METHOD=REML;
       CLASS IDnum wave;
       MODEL outcome = wave / SOLUTION DDFM=Satterthwaite;
       REPEATED wave / R RCORR TYPE=UN SUBJECT=IDnum;
       LSMEANS wave;

If an unstructured R matrix was not possible to estimate, I'd still examine the answer key for the model for the means (via a saturated means model), but estimate a random intercept only (which should always be possible):

Note the two different versions of the "time" variable in the syntax. Both are necessary here because they do different things. "**Wave**" is treated as a **categorical** predictor, and its role is to structure the **R** matrix in the event of missing data. Therefore, "wave" goes on the CLASS and REPEATED statements. In contrast, "**time**" is treated as a **continuous** predictor, and its role is to index linear effects of time (and it is centered such that wave 1 = time 0). Accordingly, in the ESTIMATE statements, only one value after "time" is needed.

Row 1 2 3 4	Estimatec Coll 2.1725	I R Matrix for Col2 2.1725	Dnum 1 Col3 2.1725	Col4 2.1725	After controlling for the fixed linear effect of time, the residual variance was reduced from $\sigma_e^2 = 7.06$ in the empty means, random intercept model to $\sigma_e^2 = 2.17$ in this model. This is a reduction of $(7.06 - 2.17) / 7.06 = .69$ (or 69% of the residual variance is accounted for by a fixed linear time).
	Estimated	l G Matrix		L L	
		IDnum:			However, the random intercept variance actually increased
		Person ID			from 2.88 to 4.10. This is because of how $\tau_{U_0}^2$ is found:
Row	Effect	number	Col1		0
1	Intercept	1	4.1026		true $\tau_{U_0}^2$ = observed $\tau_{U_0}^2 - (\sigma_e^2/n)$ So reducing σ_e^2 will make $\tau_{U_0}^2$ increase.
	Estimator	l V Matrix for	TDDum 1		So reducing o_{θ} with make v_{0_0} increase.

Note that the "time" variable gets included in the RANDOM statement, not "wave"-including "wave" would result in model non-convergence, because it would try to estimate a random slope variance for each possible difference between waves (instead of a single variance for a continuous random slope through all the waves).

Row 1 2 3 4	Col1 0.6986	d R Matrix f Col2 0.6986 timated G Ma	Col3 0.6986	Col4 0.6986	After adding a random linear effect of time, the residual variance is smaller, but it is not correct to say that it has been reduced. Random effects do not explain variance; they simply re-allocate it. Here, this means that part of what was residual is now individual differences in the linear effect of time as a new pile of variance in the G matrix below.
		IDnum: Person ID

Random Effect 95% CI = fixed effect $\pm (1.96*\sqrt{\text{Random Variance}})$

Intercept 95% CI =
$$\gamma_{00} \pm \left(1.96^* \sqrt{\tau_{U_0}^2}\right) = 10.27 \pm \left(1.96^* \sqrt{2.26}\right) = 7.32 \text{ to } 13.22$$

Linear Time Slope 95% CI = $\gamma_{10} \pm \left(1.96^* \sqrt{\tau_{U_1}^2}\right) = 1.72 \pm \left(1.96^* \sqrt{0.91}\right) = -0.15 \text{ to } 3.59$

Last but not least: there may still be residual covariances after modeling individual differences in the linear effect of time (i.e., adding a random linear slope to the G matrix). We can test alternative **R** matrix assumptions besides VC (which assumes no residual covariance/correlation over time) to see if this is the case:

           Fit Statistics
-2 Res Log Likelihood
                                366.7
                                          The -2LL is not smaller than the random linear time model, so adding a
AIC (smaller is better)
                                376.7
AICC (smaller is better)
                                377.4
                                          lag-1 covariance to the R matrix does not improve model fit, either.
BIC (smaller is better)
                                382.8
```
