

Example 3: Mediation of Within-Person Fluctuation (in Univariate MLM in SAS PROC MIXED Relative to Multivariate MLM in Mplus v.8) complete syntax, data, and output available electronically

The limitations of univariate multilevel models (MLMs) (as in SAS MIXED) can be addressed by switching to “truly” multivariate MLMs (aka, multilevel SEM, or M-SEM), as in Mplus. The primary difference is that rather than obtaining between and within effects through *observed variable predictors*, in truly multivariate MLMs the between and within *variances* of any level-1 predictor can be partitioned into level-2 random intercept variances and level-1 residual variances in the model, the same as for the DV in univariate MLMs. This example features truly multivariate MLMs in which a level-1 variable can be both a predictor and an outcome simultaneously, as is necessary in order to do multilevel mediational analysis of direct and indirect fixed effects. These models use the data from Hoffman (2015) chapter 8 examining fluctuation across 5 days for 105 older adults in daily stressors, daily negative mood, and daily physical symptoms.

Level-2, Between-Person (BP) Model:

There are two options for how to include variables in these models: (1) They can be treated as **predictors**, which is the same as in univariate MLM. This means that although the model estimates their fixed effects in predicting the outcome(s), their means, variances, and covariances are *not* model parameters, and these predictors do not have distributional assumptions. This also means that because they are *not* part of the model likelihood, **any rows with missing predictors will be deleted**. (2): They can be treated as **outcomes**, either by predicting them with other variables, or just by letting the model estimate their variances and covariances at each applicable level (and mean at the highest level). So because **outcomes are part of the model likelihood, they can have missing case-wise data given their distributional assumptions**, such that any case that has at least one outcome will still be included. Currently in Mplus, it is not possible to turn categorical predictors into outcomes when using the %BETWEEN%/ %WITHIN% syntax. For this reason, in the multivariate MLMs we will include our “X”, daily stressor (0=no, 1=yes) as an observed level-1 predictor, and its person mean (centered such that 0=.40) as an observed level-2 predictor. In contrast, our “M”, daily negative mood, and our “Y”, daily physical symptoms, will be outcomes whose variance is partitioned by the model (as shown above).

There are two ways of specifying level-1 fixed effects in Mplus, and they create different level-2 fixed effects: (1) If a level-1 fixed effect is specified directly in the level-1 %WITHIN% model, any level-2 fixed effects of the same variable will carry their total BP effects. (2) In contrast, if the level-1 placeholder syntax is used, such that the variable’s level-1 fixed and level-2 random effects show up in the level-2 %BETWEEN% model instead—regardless of whether the random slope variance is actually estimated—then the variable’s level-2 fixed effects will instead carry the BP contextual effects. We will show both versions to illustrate this result, although based on previous analyses for these data, the **WP effects in this example will be fixed only**, as no random WP effects were significant. Further, we will also examine how to specify interactions in this “truly” multivariate MLM framework, which become **latent variable interactions** for which ML estimation requires numeric integration. Finally, there is no REML within Mplus, so **we will use ML for all models**. We will first examine the effects of X and M in predicting Y separately. Then, within a full mediation model, we will examine the $X \rightarrow M$ effect and the unique effects of X and M in predicting Y.

Step 1: Fitting the Between-Person and Within-Person Stress (X) → Symptoms (Y) Effects (i.e., before controlling for M Negative Mood)

In SAS, partitioning stress into level-1 WP vs. level-2 BP contextual effects by observed variables:

```
TITLE1 "Step 1: WP and BP Contextual BP Stress
Predicting Symptoms: X --> Y";
PROC MIXED DATA=work.Example3 COVTEST NOCLPRINT IC
NAMELEN=50 METHOD=ML;
CLASS PersonID;
MODEL symptoms = women age80 women*age80
stressor PMstress40
/ SOLUTION DDFM=SATTERTHWAITE;
RANDOM INTERCEPT / TYPE=UN SUBJECT=PersonID;
ESTIMATE "BP X to Y Effect" stressor 1 PMstress40 1;
RUN;
```

In Mplus, doing the exact same thing:

```
TITLE: Step 1: Predicting symptoms outcome from OBSERVED stress (so X --> Y);
DATA: FILE = Example3.csv; ! Can just list file if in same directory;

VARIABLE:
! List of ALL variables in stacked data file, in order;
! Mplus does NOT know what they used to be called, though;
NAMES ARE PersonID women age80 session symptoms mood2 stress PMstr40;
! List of ALL variables used in model (DEFINED variables at end);
USEVARIABLES ARE symptoms women age80 stress PMstr40 agesex;
! Missing data codes (here, -999);
MISSING ARE ALL (-999);
! Identify level-2 ID;
CLUSTER = PersonID;
! Predictor variables with variation ONLY at level 1;
WITHIN = stress;
! Predictor variables with variation ONLY at level 2;
BETWEEN = age80 women agesex PMstr40;

DEFINE: agesex = age80*women; ! Create observed level-2 interaction;

ANALYSIS: TYPE IS TWOLEVEL RANDOM; ! 2-level model with random slopes;
ESTIMATOR IS ML; ! Can also use MLR for non-normality;

MODEL: ! X Stress --> Y Symptoms Model;
! Level-1, Within-Person (WP) Model;
%WITHIN%
symptoms; ! L1 R: residual variance in symptoms;
WPXtoY | symptoms ON stress; ! Placeholder for L1 WP stress->symptoms;

! Level-2, Person-Level Model;
%BETWEEN%
[symptoms]; ! Fixed intercept for symptoms;
symptoms; ! L2 random intercept variance in symptoms;

[WPXtoY] (WPXtoY); ! L1 WP fixed effect (label) of stress->symptoms;
WPXtoY@0; ! L2 G: No random stress slope variance->symptoms;

symptoms ON women (SextoY); ! BP total fixed effect of women->symptoms;
symptoms ON age80 (AgetoY); ! BP total fixed effect of age->symptoms;
symptoms ON agesex (AgesexY); ! BP total fixed effect of age*women->symptoms;
symptoms ON PMstr40 (conXtoY); ! Contextual BP fixed effect of stress->symptoms;

MODEL CONSTRAINT: ! Equivalent to ESTIMATE in SAS;
NEW(BPXtoY); ! Need to name each new created fixed effect;
BPXtoY = WPXtoY + conXtoY; ! BP total effect of stress->symptoms;
```

SAS Univariate Results: This is the exact same model in SAS MIXED and Mplus MLM because both treat daily stressors and person mean stressors as observed predictors and symptoms as a model-estimated outcome.

BPSTRESS	1.445	0.286	5.046	0.000

Step 2: Fitting the Between-Person and Within-Person Mood (M) → Symptoms (Y) Effects (i.e., before controlling for X Symptoms)

In univariate SAS, partitioning mood into level-1 WP vs. level-2 BP contextual effects through observed variables:

```
TITLE1 "Step 2: WP and BP Contextual Mood
Predicting Symptoms: M --> Y";
PROC MIXED DATA=work.Example3 COVTEST NOCLPRINT IC
NAMELEN=50 METHOD=ML;
CLASS PersonID;
MODEL symptoms = women age80 women*age80 mood2 PMmood2
/ SOLUTION DDFM=SATTERTHWAITTE;
RANDOM INTERCEPT / TYPE=UN SUBJECT=PersonID;
ESTIMATE "BP M to Y Effect" mood2 1 PMmood2 1;
RUN;
```

SAS Results: Although this is the same idea, this is NOT the same model as in Mplus, in which mood is treated like another DV (and so its mean and two variances are model parameters, even though it is not being predicted).

Step 3: Fitting the Full Mediation Model: Between-Person and Within-Person Stress (X) → Mood (M) → Symptoms (Y)
 For parallel interpretation of the level-2 fixed effects of stress, sex, age, and their interaction also now predict mood.

A full simultaneous mediation model is not possible in univariate SAS, so here is Multivariate Mplus using placeholder syntax → WP + BP Contextual effects:

```

TITLE: Step3: Full mediation MLM of Stress --> Mood --> Symptoms;
( DATA is the same )
VARIABLE:
! List of ALL variables in stacked data file, in order;
  NAMES ARE PersonID women age80 session symptoms
           mood2 stress PMstr40;
! List of ALL variables used in model (DEFINED variables at end);
  USEVARIABLES ARE symptoms women age80
           mood2 stress PMstr40 agesex;
! Missing data codes (here, -999);
  MISSING ARE ALL (-999);
! Identify level-2 ID;
  CLUSTER = PersonID;
! Predictor variables with variation ONLY at level 1;
  WITHIN = stress;
! Predictor variables with variation ONLY at level 2;
  BETWEEN = age80 women agesex PMstr40;
( DEFINE and ANALYSIS are the same )

MODEL:      ! Full X Stress --> M Mood --> Y Symptoms Mediation Model
! Level-1, Within-Person (WP) Model;
%WITHIN%
  symptoms;           ! L1 R: residual variance in symptoms;
  mood2;              ! L1 R: residual variance in mood;
  WPXtoM | mood2      ON stress; ! Placeholder L1 WP stress->mood;
  WPXtoY | symptoms ON stress; ! Placeholder L1 WP stress->symptoms;
  WPMtoY | symptoms ON mood2;  ! Placeholder L1 WP mood->symptoms;

! Level-2, Person-Level Model;
%BETWEEN%
[symptoms];           ! Fixed intercept for symptoms;
  symptoms;           ! L2 random intercept variance in symptoms;
[mood2];              ! Fixed intercept for mood;
  mood2;              ! L2 random intercept variance in mood;
[WPXtoM] (WPXtoM);    ! L1 WP fixed effect of stress->mood;
  WPXtoM@0;           ! L2 G: No random stress slope variance->mood;
[WPXtoY] (WPXtoY);    ! L1 WP fixed effect of stress->symptoms;
  WPXtoY@0;           ! L2 G: No random stress slope variance->symptoms;
[WPMtoY] (WPMtoY);    ! L1 WP fixed effect of mood->symptoms;
  WPMtoY@0;           ! L2 G: No random mood slope variance->symptoms;

symptoms mood2 ON women; ! BP total fixed effects women->mood, symptoms;
symptoms mood2 ON age80; ! BP total fixed effects age->mood, symptoms;
symptoms mood2 ON agesex; ! BP total fixed effects age*women;

mood2      ON PMstr40 (conXtoM); ! Context BP fixed effect stress->mood;
symptoms ON PMstr40 (conXtoY); ! Context BP fixed effect stress->symptoms;
symptoms ON mood2 (conMtoY); ! Context BP effect of mood->symptoms;

```

```

! Getting BP total fixed effects and all indirect effects;
MODEL CONSTRAINT:
NEW(BPXtoM BPXtoY BPMtoY WPind Conind BPind);
! BP effects;
  BPXtoM = WPXtoM + conXtoM; ! BP total effect stress->mood;
  BPXtoY = WPXtoY + conXtoY; ! BP total effect stress->symptoms;
  BPMtoY = WPMtoY + conMtoY; ! BP effect of mood->symptoms;
! Indirect effects;
  WPind = WPXtoM*WPMtoY;      ! WP indirect effect;
  Conind = conXtoM*conMtoY;    ! BP contextual indirect effect;
  BPind = BPXtoM*BPMtoY;      ! BP total indirect effect;

```

Note: MODEL INDIRECT is the usual way of obtaining indirect effects in Mplus, but is not available for multilevel models. So we are using MODEL CONSTRAINT to calculate the indirect effects ourselves to accomplish the same thing. Further, although one can get bootstrapped *p*-values and confidence intervals for single-level mediation models, they are not available for multilevel mediation models. That means the *p*-values from the indirect effects may be a little suspect, and other methods of assessing significance may be needed for “best practice” (see Kris Preacher’s website for online tools for bootstrapping parameter estimates).

Step 4: Same Model, Adding Mood*Sex Interactions → Symptoms

When I tried to estimate a latent variable interaction between level-2 observed variable women and level-2 random intercept mood2, Mplus insisted that was an observed variable interaction, which would instead be between original level-1 mood and women. So I had to create a work-around that involved renaming the mood random intercept:

```
( all previous commands are the same )  
  
MODEL:      ! Full X Stress --> M Mood --> Y Symptoms Mediation Model + Mood*Sex  
! Level-1, Within-Person (WP) Model;  
%WITHIN%  
  symptoms;      ! L1 R: residual variance in symptoms;

Step 4: Same Model, Adding Mood*Sex Interactions → Symptoms

When I tried to estimate a latent variable interaction between level-2 observed variable women and level-2 random intercept mood2, Mplus insisted that was an observed variable interaction, which would instead be between original level-1 mood and women. So I had to create a work-around that involved renaming the mood random intercept:

(all previous commands are the same)

```

Example Results Section for Steps 1 to 3:

The relationships among time-varying stressors (i.e., whether or not a stressor was reported on a given day), negative mood (constructed as the mean of five items), and physical symptoms (constructed as the sum of five reported symptoms) were examined using multivariate multilevel models (i.e., multilevel structural equation modeling) within Mplus v. 8 (Muthén & Muthén, 1998-2017) using maximum likelihood (ML) estimation. (We obtained an identical pattern of results using a robust ML estimator to account for potential non-normality and so the original ML results are reported below.) Two observed variables were used to partition the effect of binary daily stressors (0=no, 1=yes) into its contextual (level-2; incremental between-person) and within-person (level-1) effects, in which the level-2 predictor was created as the person mean of stressors centered at 40% of days ($PMstress_i - .40$) and the level-1 predictor was daily stressor variable. This same type of variance partitioning was accomplished within the model estimation for the continuous level-1 outcomes of negative mood and physical symptoms, such that random intercept variances were estimated for each at level 2, and residual variances were estimated for each at level 1. Under this specification, level-1 fixed effects indicate within-person effects, whereas level-2 fixed effects reflect contextual effects. Accordingly, MODEL CONSTRAINT command was used to obtain model-implied between-person effects and all indirect effects. Age, sex, and their interaction (with 80-year-old men as the reference group) were included as predictors in the level-2 model for both negative mood and physical symptoms. In addition, likelihood ratio revealed no significant random within-person direct effects in any of the models (all $-2\Delta LL(\sim 2) < 5.99$, $p > .05$), and so all within-person direct effects were fixed across persons. Although our eventual goal was to examine the extent to which negative mood mediated the between-person and within-person effects of stressors on physical symptoms, we began by estimating separate models for stress and mood each predicting symptoms before controlling for each effect for the other.

First, a univariate multilevel model of observed stressors predicting physical symptoms ($X \rightarrow Y$) revealed significant positive contextual (1.335) and between-person (1.445) effects but no significant within-person effect. Thus, after controlling for age and sex but before controlling for negative mood, physical symptoms were higher on average for persons who experienced more stressor days than others (even after controlling for daily stressors), but physical symptoms on a given day were not related to whether a stressor was experienced that day. Second, a separate multivariate multilevel model of negative mood predicting physical symptoms ($M \rightarrow Y$) revealed significant contextual (2.339) and between-person (2.506) effects but no significant within-person effect. Thus, after controlling for age and sex but before controlling for stressors, physical symptoms were higher on average for persons who reported higher negative mood than others (even after controlling for daily negative mood), but physical symptoms on a given day were not related to whether a negative mood was higher than usual that day. Thus, to summarize, significant direct effects were found between persons (at level 2) for both $X \rightarrow Y$ and $M \rightarrow Y$, but no significant direct effects were found within persons.

Finally, the extent to which daily negative mood mediated the relationship between daily stressors and daily physical symptoms at each level was examined in a multilevel mediation model with all three variables, each specified as previously described. For comparable interpretation of the level-2 effects of stressors on mood and symptoms, level-2 effects of age, sex, and their interaction were added to predict negative mood (as well as symptoms, as before). Results are shown in Table X. At level 2, although there was a significant positive between-person effect (0.286) of observed stressors predicting negative mood ($X \rightarrow M$), the corresponding contextual effect (0.124) was not significant, indicating that negative mood was not significantly higher in persons with more stressor days after controlling for daily stressors. In addition, the between-person effect of stressors on physical symptoms ($X \rightarrow Y$) was significantly reduced (from 1.445 to 1.175) after controlling for the between-person effect of negative mood, as indicated by a significant between-person indirect effect of stressors on physical symptoms through negative mood. Likewise, the between-person effect of negative mood on physical symptoms ($M \rightarrow Y$) was reduced (from 2.506 to 1.852) after controlling for stressors. Both between-person effects of stressors and negative mood predicting symptoms (and their contextual effects) remained uniquely significant. Thus, reporting more stressor days than others is related to reporting more physical symptoms than others (even after controlling for daily stressors), but this link did not result solely from a concomitant difference in negative mood. However, the contextual indirect effect was not significant, indicating that some of this mediation is reduced after controlling for daily stressors and daily negative mood. At level 1, there was a significant $X \rightarrow M$ within-person effect (0.162), indicating that greater stressors than usual on a given day did predict greater negative mood than usual that day. However, the within-person effect of stressors on physical symptoms ($X \rightarrow Y$) was not significantly reduced (and was still not significant) after controlling for negative mood, as indicated by a nonsignificant within-person indirect effect of stressors on physical symptoms through negative mood. Thus, after controlling for people's general tendencies to do so, reporting a stressor did not predict reporting more physical symptoms that day. Finally, the within-person effect of negative mood on symptoms ($M \rightarrow Y$) remained nonsignificant after controlling for stressors as well.

Equation for Step 3 written during the workshop:

Level 1: $Mood_{ti} = \beta_{0iM} + \beta_{1iM}(Stress_{ti}) + e_{tiM}$

Level 1: $Symptoms_{ti} = \beta_{0iY} + \beta_{1iY}(Stress_{ti}) + \beta_{2iY}(Mood_{ti}) + e_{tiY}$

Level 2:

$$\beta_{0iM} = \gamma_{00M} + \gamma_{01M}(Age_i - 80) + \gamma_{02M}(Women_i) + \gamma_{04M}(Women_i)(Age_i - 80) + \gamma_{05M}(PMstressor_i - .40) + U_{0iM}$$

$$\beta_{1iM} = \gamma_{10M}$$

Level 2:

$$\beta_{0iY} = \gamma_{00Y} + \gamma_{01Y}(Age_i - 80) + \gamma_{02Y}(Women_i) + \gamma_{04Y}(Women_i)(Age_i - 80) + \gamma_{05Y}(PMstressor_i - .40) + \gamma_{06Y}(Mood_i) + U_{0iY}$$

$$\beta_{1iY} = \gamma_{10Y}$$

$$\beta_{2iY} = \gamma_{20Y}$$

Step 5: Fitting the Full Mediation Model via SEM: Between-Person and Within-Person Stress (X) → Mood (M) → Symptoms (Y)

Level-1 stress now must be treated as an outcome, which means this model is not equivalent to the previous Step 3 in MLM

TITLE: Step 5: SEM Full Mediation Model using Stress Intercept Factor

WPind = WPXtoM*WPMtoY; ! WP indirect effect;

Conind = conXtoM*conMtoY; ! BP contextual indirect effect;

BPind = BPXtoM*BPMtoY; ! BP total indirect effect;

Note: We are again using MODEL CONSTRAINT to calculate the indirect effects ourselves. Further, although one can get bootstrapped *p*-values and confidence intervals for single-level mediation models, they are not available for multilevel mediation models. That means the *p*-values from the indirect effects may be a little suspect, and other methods of assessing significance may be needed for “best practice” (see Kris Preacher’s website for online tools for bootstrapping parameter estimates).
