

# Crossed Random Effects for Other (Not Longitudinal) Repeated Measures Designs

- Topics:
  - **ANOVA for repeated measures**
  - MLM for repeated measures

# Analytic Toolbox of the Experimental Psychologist

- Our friend, analysis of variance (ANOVA)
  - Between-group (*aka* between-subject, independent IV)
  - Within-group (*aka* within-subject, dependent, repeated measures IV)
  - Split-plot (*aka* mixed design of between- and within-group IVs)
- Expandable to include:
  - multiple IVs (factorial ANOVA)
  - main effects of continuous covariates (ANCOVA)
  - multiple outcomes (MANOVA/MANCOVA)

# ANOVA works well when...

- Experimental stimuli are **controlled** and **exchangeable**
  - Controlled → Constructed, not sampled from a population
  - Exchangeable → Stimuli vary only in dimensions of interest
  - ...What to do with non-exchangeable stimuli (e.g., words, scenes)?
- Experimental manipulations create **discrete conditions**
  - e.g., set size of 3 vs. 6 vs. 9 items
  - e.g., response compatible vs. incompatible distractors
  - ...What to do with *continuous* item predictors (e.g., time, salience)?
- One has **complete data**
  - e.g., if outcome is RT and accuracy is near ceiling
  - e.g., if responses are missing for no systematic reason
  - ...What if data are not missing completely at random (e.g., inaccuracy)?

# Motivating Example: Psycholinguistic Study Designs

- Word Recognition Tasks (e.g., Lexical Decision)
  - Word lists are constructed based on targeted dimensions while controlling for other relevant dimensions
  - Outcome = RT to decide if the stimulus is a word or non-word (accuracy is usually near ceiling)
- Tests of effects of experimental treatment are typically conducted with the person as the unit of analysis...
  - Average the responses over words within conditions
    - Contentious fights with reviewers about adequacy of experimental control when using real words as stimuli
    - Long history of debate as to how words as experimental stimuli should be analyzed...  $F_1$  ANOVA or  $F_2$  ANOVA (or both)?
    - $F_1$  only creates a “Language-as-Fixed-Effects Fallacy” (Clark, 1973)

# ANOVAs on Summary Data

## Original Data per Subject

|    | B1        | B2        |
|----|-----------|-----------|
| A1 | Trial 001 | Trial 101 |
|    | Trial 002 | Trial 102 |
|    | .....     | .....     |
|    | Trial 100 | Trial 200 |
| A2 | Trial 201 | Trial 301 |
|    | Trial 202 | Trial 302 |
|    | .....     | .....     |
|    | Trial 300 | Trial 400 |

## Subject Summary Data

|    | B1            | B2            |
|----|---------------|---------------|
| A1 | Mean (A1, B1) | Mean (A1, B2) |
| A2 | Mean (A2, B1) | Mean (A2, B2) |

## "F<sub>1</sub>" Repeated Measures ANOVA on *N* subjects:

$$RT_{cs} = \gamma_0 + \gamma_1 A_c + \gamma_2 B_c + \gamma_3 A_c B_c + \mathbf{U}_{0s} + e_{cs}$$

## "F<sub>2</sub>" Between-Groups ANOVA on *T* trials:

$$RT_t = \gamma_0 + \gamma_1 A_t + \gamma_2 B_t + \gamma_3 A_t B_t + e_t$$

## Trial Summary Data

|        | B1  |
|--------|---|
| A1, B1 | Trial 001 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>Trial 002 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>..... Trial 100 |
| A1, B2 | Trial 101 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>Trial 102 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>..... Trial 200 |
| A2, B1 | Trial 201 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>Trial 202 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>..... Trial 300 |
| A2, B2 | Trial 301 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>Trial 302 = Mean(Subject 1, Subject 2,... Subject <i>N</i> )<br>..... Trial 400 |

# Choosing Amongst ANOVA Models

- $F_1$  RM ANOVA on **subject** summary data:
  - Assumes trials are fixed—within-condition **trial** variability is gone
- $F_2$  ANOVA on **trial** summary data:
  - Assumes persons are fixed—within-trial **subject** variability is gone
- Proposed ANOVA-based resolutions:
  - **F'** → quasi-F test that treats both trials and subjects as random (Clark, 1973), but requires complete data (least squares)
  - **Min F'** → lower-bound of F' derived from F1 and F2 results, which does not require complete data, but is (too) conservative
  - **F<sub>1</sub> x F<sub>2</sub> criterion** → effects are only “real” if they are significant in **both F<sub>1</sub> and F<sub>2</sub> models** (aka, death knell for psycholinguists)
  - But neither model is complete (two wrongs don't make a right)...

# Sources of Variance (Clark, 1973)

*t = #conditions, i = #items, s = #subjects*

| Label     |                                     | DF          | Expected Mean Square   |
|-----------|-------------------------------------|-------------|--|
| T         | Treatments (t)                      | t-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + s\sigma_I^2 + i\sigma_T^2$ |
| I w T     | Items (i) within Treatments         | t(i-1)      | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + s\sigma_I^2 + \text{---}$              |
| S         | Subjects (s)                        | s-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + t\sigma_S^2 + \text{---} + \text{---}$              |
| T x S     | Treatments by Subjects              | (t-1)(s-1)  | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + \text{---} + \text{---}$   |
| S x I w T | Subjects by Items within Treatments | t(i-1)(s-1) | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + \text{---} + \text{---}$               |

# Effect of Treatment via $F_1$ ANOVA

*T numerator should differ from TxS denominator by 1 term*

| Label     |                                     | DF          | Expected Mean Square  |
|-----------|-------------------------------------|-------------|---|
| T         | Treatments (t)                      | t-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + \boxed{s\sigma_I^2} + \boxed{is\sigma_T^2}$ |
| I w T     | Items (i) within Treatments         | t(i-1)      | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + s\sigma_I^2 + \text{---}$                               |
| S         | Subjects (s)                        | s-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + t\sigma_S^2 + \text{---} + \text{---}$                               |
| T x S     | Treatments by Subjects              | (t-1)(s-1)  | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + \text{---} + \text{---}$                    |
| S x I w T | Subjects by Items within Treatments | t(i-1)(s-1) | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + \text{---} + \text{---}$                                |

# Effect of Treatment via $F_2$ ANOVA

*T numerator should differ from I x T denominator by 1 term*

| Label     |                                     | DF          | Expected Mean Square   |
|-----------|-------------------------------------|-------------|--|
| T         | Treatments (t)                      | t-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + s\sigma_I^2 + i\sigma_T^2$ |
| I w T     | Items (i) within Treatments         | t(i-1)      | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + s\sigma_I^2 + \text{---}$              |
| S         | Subjects (s)                        | s-1         | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + t\sigma_S^2 + \text{---} + \text{---}$              |
| T x S     | Treatments by Subjects              | (t-1)(s-1)  | $\sigma_e^2 + \sigma_{S \times I}^2 + i\sigma_{T \times S}^2 + \text{---} + \text{---} + \text{---}$   |
| S x I w T | Subjects by Items within Treatments | t(i-1)(s-1) | $\sigma_e^2 + \sigma_{S \times I}^2 + \text{---} + \text{---} + \text{---} + \text{---}$               |

# Simultaneous Quasi-F Ratio (F')

- F' was proposed by Clark (1973) as a quasi-F test that treats both items and subjects as random factors

$$F'(df_{\text{num}}, df_{\text{den}}) = \frac{MS_T + MS_{S \times I}}{MS_{T \times S} + MS_I}$$

$$\text{where } df_{\text{num}} = \frac{(MS_T + MS_{S \times I})^2}{\frac{MS_T}{df_T} + \frac{MS_{S \times I}}{df_{S \times I}}} \text{ and } df_{\text{den}} = \frac{(MS_{T \times S} + MS_I)^2}{\frac{MS_{T \times S}}{df_{T \times S}} + \frac{MS_I}{df_I}}$$

$$F'(df_{\text{num}}, df_{\text{den}}) = \frac{(2 * \sigma_e^2) + (2 * \sigma_{S \times I}^2) + (\#I * \sigma_{T \times S}^2) + (\#S * \sigma_I^2) + (\#I * \#S * \sigma_T^2)}{(2 * \sigma_e^2) + (2 * \sigma_{S \times I}^2) + (\#I * \sigma_{T \times S}^2) + (\#S * \sigma_I^2)}$$

- Numerator then exceeds the denominator by exactly the treatment variance as desired... except it requires complete data given that it relies on least squares
  - Not feasible in most real-world experiments

# Minimum of Quasi-F Ratio (Min F')

- Min F' was developed to be used from  $F_1$  and  $F_2$  results:

$$\min F'(\text{df}_{\text{num}}, \text{df}_{\text{den}}) = \frac{MS_T}{MS_{T \times S} + MS_I} = \frac{F_1 * F_2}{F_1 + F_2}$$

- But given that Min F' is overly conservative, having to show significance by both models is often required instead:
  - the  $F_1$  by  $F_2$  criterion... but two wrongs don't make a right
- Wouldn't it be nice if we had some way to treat subjects and items as the random effects they actually are???
  - And to assess the extent to which items are actually exchangeable?
  - And that all the extraneous item variables were adequately controlled?
  - **Multilevel models to the rescue! ... maybe?**

# Crossed Random Effects for Other (Not Longitudinal) Repeated Measures Designs

- Topics:
  - ANOVA for repeated measures
  - **MLM for repeated measures**

# Multilevel Models to the Rescue?

## Original Data per Person

|    | B1   | B2  |
|----|--|---|
| A1 | Trial 001<br>Trial 002<br>.....<br>Trial 100 | Trial 101<br>Trial102<br>.....<br>Trial 200 |
| A2 | Trial 201<br>Trial 202<br>.....<br>Trial 300 | Trial 301<br>Trial302<br>.....<br>Trial 400 |

## Pros:

- Use all original data, not summaries
- Responses can be missing at random
- Can include continuous trial predictors

## Cons:

- **Is still wrong**

$$\text{Level 1: } y_{ts} = \beta_{0s} + \beta_{1s}A_{ts} + \beta_{2s}B_{ts} + \beta_{3s}A_{ts}B_{ts} + e_{ts}$$

$$\text{Level 2: } \beta_{0s} = \gamma_{00} + U_{0s}$$

$$\beta_{1s} = \gamma_{10}$$

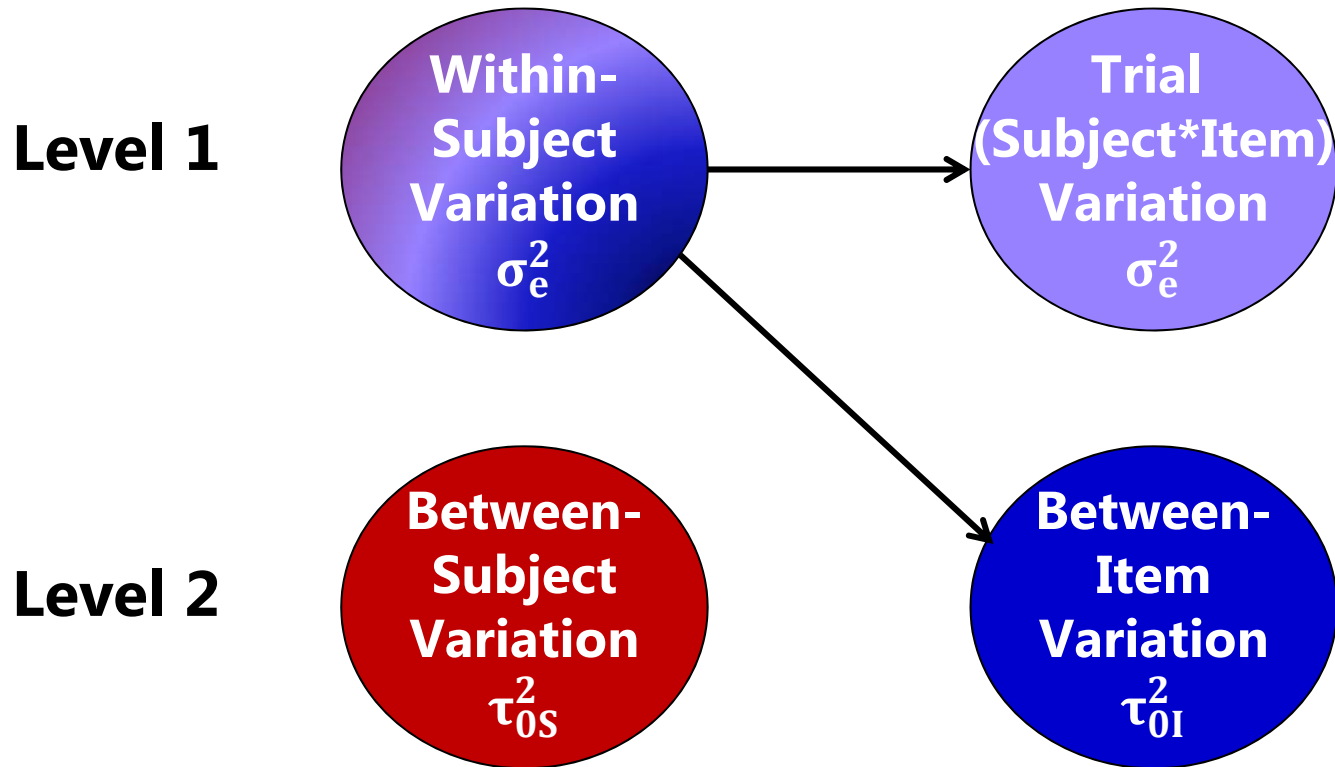

$$\beta_{2s} = \gamma_{20}$$

$$\beta_{3s} = \gamma_{30}$$

Level 1 = Within-Subject Variation  
(Across Trials)

Level 2 = Between-Subject Variation

# Multilevel Models to the Rescue?

# Empty Means, Crossed Random Effects Models

- **Residual-only model:**

- $RT_{tis} = \gamma_{000} + e_{tis}$
- Assumes no effects (dependency) of subjects or items

- **Random subjects model:**

- $RT_{tis} = \gamma_{000} + \mathbf{U}_{00s} + e_{tis}$
- Models systematic mean differences **between subjects**

- **Random subjects and items model:**

- $RT_{tis} = \gamma_{000} + U_{00s} + \mathbf{U}_{0io} + e_{tis}$
- Also models systematic mean differences **between items**

# A Better Way of (Multilevel) Life

Between-Subject Variation  
L2  $\tau_{0s}^2$

Between-Item Variation  
L2  $\tau_{0i}^2$

Trial (Subject\*Item) Variation  
 $\sigma_e^2$

Random effects over **subjects** of **item** or **trial** predictors can also be tested and predicted.

- **Multilevel Model with *Crossed* Random Effects:**

$$RT_{tis} = \gamma_{000} + \gamma_{010}A_i + \gamma_{020}B_i + \gamma_{030}A_iB_i + \mathbf{U}_{00s} + \mathbf{U}_{0i0} + \mathbf{e}_{tis}$$

$t$  trial  
 $i$  item  
 $s$  subject

- Both **subjects** and **items** as random effects:

- Subject predictors explain between-subject mean variation:  $\tau_{0s}^2$
- Item predictors explain between-item mean variation:  $\tau_{0i}^2$
- Trial predictors explain trial-specific residual variation:  $\sigma_e^2$

# Example Psycholinguistic Study

(Locker, Hoffman, & Bovaird, 2007)

- Crossed design: 38 subjects by 39 items (words or nonwords)
- Lexical decision task: RT to decide if word or nonword
- 2 word-specific predictors of interest:
  - A: Low/High Phonological Neighborhood Frequency
  - B: Small/Large Semantic Neighborhood Size

# Tests of Fixed Effects by Model

|   | A: Frequency<br>Marginal Main<br>Effect | B: Size<br>Marginal Main<br>Effect | A*B: Interaction<br>of Frequency<br>by Size |
|---|---|------------------------------------|---|
| <b>F<sub>1</sub> Subjects<br/>ANOVA</b> | $F(1,37) = 16.1$<br>$p = .0003$         | $F(1,37) = 14.9$<br>$p = .0004$    | $F(1,37) = 38.2$<br>$p < .0001$             |
| <b>F<sub>2</sub> Words<br/>ANOVA</b>    | $F(1,35) = 5.3$<br>$p = .0278$          | $F(1,35) = 4.5$<br>$p = .0415$     | $F(1,35) = 5.7$<br>$p = .0225$              |

# Conclusions

- An ANOVA model may be less than ideal when:
  - Stimuli are not completely controlled or exchangeable
  - Experimental conditions are not strictly discrete
  - Missing data may result in bias, a loss of power, or both
- ANOVA is a special case of a more general family of multilevel models (with nested or crossed effects as needed) that can offer additional flexibility:
  - Useful in addressing statistical problems →
    - Dependency, heterogeneity of variance, unbalanced or missing data
    - Examine predictor effects pertaining to each source of variation more accurately given that all variation is properly represented in the model
  - Useful in addressing substantive hypotheses →
    - Examining individual differences in effects of experimental manipulations
